```

Let's look at the overall distribution of weight change and the distributions by Diet type:

```
# overall
hist(diet_df$Weight_Change)
```

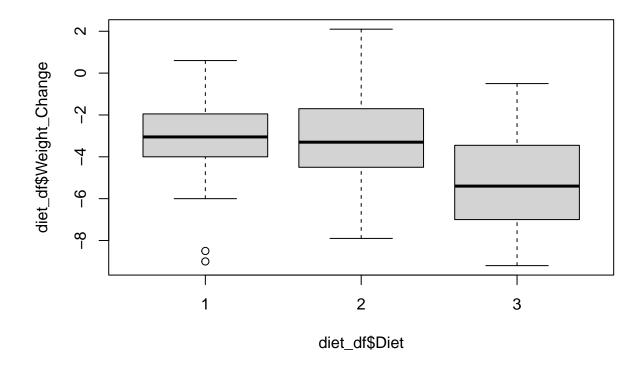

Histogram of diet_df\$Weight_Change

boxplot(diet_df\$Weight_Change)

by diet type boxplot(diet_df\$Weight_Change~diet_df\$Diet)

We can observe that Weight_Change seems to follow a normal distribution (we'll later learn how to test normality of a variable). Moreover, diet 3 seems to result in a higher decrease compared to diets 1 & 2. We'll test the difference between mean weight changes between diet 1 and 3 in the next section. For now, let's test whether the overall mean weight change is significantly different than -3.

1. Check assumptions, determine H_0 and H_a , choose α

Inspecting the histogram of overall weight change, we concluded that it is normally-distributed.

$$H_0: \mu = -3$$
 and $H_a: \mu \neq -3$

Let's choose $\alpha = 0.05$

2. Calculate the appropriate test statistic

$$t_H = \frac{\bar{X} - \mu}{s/\sqrt{n}}$$

t_stat <- (mean(diet_df\$Weight_Change) - (-3)) / (sd(diet_df\$Weight_Change) / sqrt(nrow(diet_df)))
t_stat</pre>

3. Calculate critical values/p value

Critical values

```
C1 <- qt(0.05/2, df = df)

C2 <- qt(1 - 0.05/2, df = df)

C1; C2

## [1] -1.9913

## t_stat in rejection zone?

t_stat < C1 | t_stat > C2

## [1] TRUE

p value

p_val <- 2 * (1 - pt(abs(t_stat), df = df))
```

[1] 0.0045304

p_val

Confidence Interval

The 95% Confidence Interval for μ :

95%
$$CI = [\bar{X} + t_{\alpha/2} \frac{s}{\sqrt{n}}, \ \bar{X} + t_{1-\alpha/2} \frac{s}{\sqrt{n}}]$$

```
SE <- sd(diet_df$Weight_Change) / sqrt(nrow(diet_df))

mean(diet_df$Weight_Change) + C1 * SE; mean(diet_df$Weight_Change) + C2 * SE
```

[1] -4.4201 ## [1] -3.2696

4. Decide whether to reject/fail to reject H_0

- The calculated test statistic falls within the rejection region
- p value $< \alpha$

We reject the null hypothesis.

"With 95% confidence, there is enough evidence to say mean weight change is significantly different than 0."

"The overall mean weight change was found to be significantly different than -3 (t-test p < 0.001, 95% CI =

$$-4.42, -3.27$$

)"

Using t.test()

```
?t.test
t.test(diet_df$Weight_Change, mu = -3)
```

```

Paired t-Test

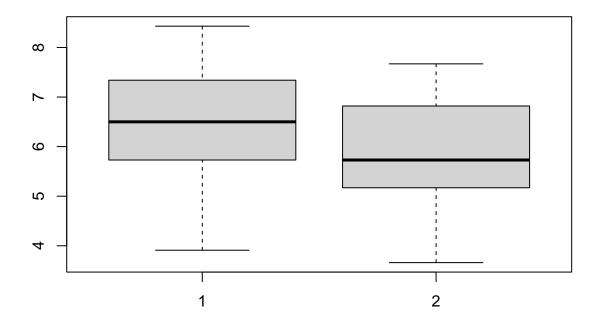

A study tested whether cholesterol was reduced after using a certain brand of margarine as part of a low fat, low cholesterol diet. The subjects consumed on average 2.31g of the active ingredient, stanol easter, a day. This data set contains information on 18 people using margarine to reduce cholesterol over three time points.

```

```

For the overall data, let's compare whether there is a significant change between Before and After8weeks: boxplot(chol_df\$Before, chol_df\$After8weeks)

check normality hist(chol_df\$After8weeks - chol_df\$Before)

Histogram of chol_df\$After8weeks - chol_df\$Before

chol_df\$After8weeks - chol_df\$Before

```
t.test(chol_df$After8weeks, chol_df$Before, paired = TRUE)
```

```
##
## One Sample t-test
##
## data: chol_df$After8weeks - chol_df$Before
## t = -14.9, df = 17, p-value = 3.3e-11
## alternative hypothesis: true mean is not equal to 0
## 95 percent confidence interval:
## -0.71766 -0.54011
## sample estimates:
## mean of x
## -0.62889
```
